

Pepper AI Builder : Assignment

THE PROBLEM

Every employee on Pepper's Customer Success team spends 4+ hours a week building reports for clients.

How would you solve this?

A BIT OF CONTEXT

Pepper Atlas is an AI-native platform that helps clients manage their organic and AI search visibility. CS managers today pull data from a handful of sources, stitch it together in spreadsheets and decks, and email it to clients on a recurring cadence.

DATA AVAILABLE

See the attached workbook: **Data Available - Interview.xlsx**. It documents endpoints across 7 sources (GSC, GA4, Semrush, GEO, WordPress, Webflow, Contentful) each with inputs, outputs, and what each field means.

- Treat them as black-box APIs — assume they return realistic data. No real calls required.
- You don't need every endpoint. Pick what you actually need.
- If your solution needs something not listed, say what you'd add and why.

WHAT "DONE" LOOKS LIKE

- Working prototype - code, notebook, or agent that produces a real output (a report, a draft, a recommendation).
- UX flow - a clickable artifact (Claude / Figma / HTML) showing the experience: who sees what, when, and how.
- Eval / experiment design - how would you know if your solution actually saves the 4 hours? Define the measurement, dataset, and success criteria.
- Product Requirement Doc - a document highlighting what the product is expected to do; a common source of knowledge to be shared across teams for building the product in Atlas.

CONSTRAINTS & NON-GOALS

- Skip auth, billing, and dashboard chrome - assume those exist.
- You can use any source.
- Focus more on competitor research and back any other assumptions with publicly available data.
